Overview

This note describes the how to do the technical integration between PayUMoney Payment Gateway and your website in respect of powering online transactions.

PayUMoney Payment Gateway

PayUMoney offers electronic payment service to your website through its various partnerships with banks and payment instrument companies. Through PayUMoney, your clients would be able to make electronic payments through credit card, debit card and online net banking account

PayUMoney also offers an online interface where the merchant can view transaction details, settlement reports, analytic reports etc. This online interface can be accessed through https://www.payumoney.com by using the username and password provided to you.

Payment and Settlement Process

The following diagram explains how the customer makes the payment and how the split settlement happens in the sub-merchants' accounts:

Marketplace Settlement Flow
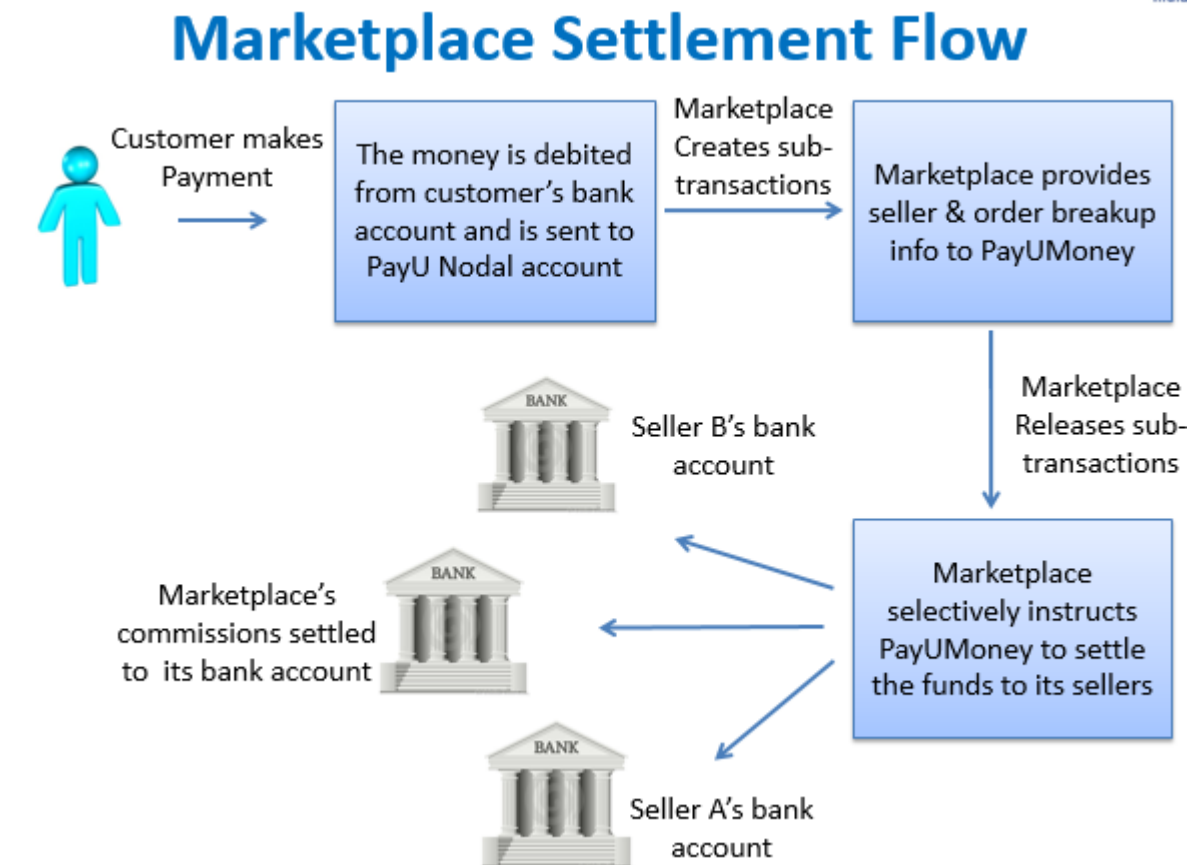

Status of a Transaction

A transaction can have several different statuses as explained below.

1. **Not Started** – The transaction has not been started yet.
2. **Initiated** – The transaction has been started but not completed.
3. **Money With PayUMoney**– The transaction was successful and the transaction amount is with PayUMoney.
4. **Refunded** – The entire amount of the transaction has been refunded.
5. **Partially Refunded** – A part of the amount of the transaction has been refunded.
6. **Bounced** – Incomplete or no details provided at PayUMoney payment page.
7. **Failed** – The transaction didn't complete due to a failure.
8. **Settlement in Process** – Settlement for the transaction is in process.
9. **Completed** – The transaction is settled and complete.

Settlement process

Settlement is the process by which the money gets transferred from the customer to the bank account of the merchant.

There is a reconciliation process at PayUMoney. On the next day, after you have captured the transactions, PayUMoney will reconcile the online transactions with the credits received based on batch files received from the banks. After reconciling, we will generate a report and payment will be made for all the transactions for which payment has been received from the bank. All the details will be visible to you in the online interface.

Technical Integration

In the payment process flow, to move the consumer from Step 1 to Step 2, a POST request needs to be generated by merchant to the following URL

Production server:

POST URL: https://secure.payu.in/_payment

To post successfully on production server, your merchant application status should be approved and you should use the key sent to you by PayUMoney after confirming the approval of your application.

Test server:

POSL URL: https://test.payu.in/_payment

Test Key – Will provided when test account is created

Test Salt – Will provided when test account is created

Test Card Name: any name

Test Card Number: 5123456789012346

Test CVV: 123

Test Expiry: May 2017

In order to integrate your website with PayUMoney, you can use our test server and test key if your application is not yet approved.

Please note that the Key and Salt for test server are different and should be used only with test server.

The purpose of the test server & Key-Salt is to enable you to integrate and do test transaction. It cannot be used for actual transactions from your website.

Key notes and terms

1. **Key (MerchantID)** : This ID is generated at the time of activation of your site and helps to uniquely identify you to PayUMoney.

2. **TxnID**: A Unique alphanumeric Transaction ID generated by you to uniquely identify a transaction. The TxnID should be unique since it would allow you to identify the transaction easily.

3. **Amount:** Amount is the total amount of the transaction (greater than 0) in INR, without a currency symbol or other non-numeric character. Only a decimal allowed.

4. **MIHPayID**: Unique ID generated for a transaction by PayU.in

5. **Hash (Checksum)**: This refers to a random numeric string generated using a mathematical algorithm to ensure that data is not tampered along the way. Let's say a message has to be sent from location X to Y. X and Y both mutually agree on a Secret Key called "Salt" that only both of them possess. A checksum is generated by a mathematical function using the message and the Salt as input. This checksum is then sent along with the message to Y. Y then recalculates this checksum using the Salt and the same algorithm. If the checksum that Y calculates is different from the checksum that X passed then the data was tampered along the way and is thus rejected.

   The Checksum algorithm used is SHA2 which is globally well known algorithm. To need help with implementation, feel free to call us, mail us or use Google to find the desired function library for your implementation. Some example codes are also mentioned at the end of this document

6. **Product Info**: In productinfo parameter you need to specify how the payment will be split. The required information should be passed json format. You need to specify the following information –

Parameter	Is required	Description
Name	Mandatory	The unique ID assigned to that particular split.
merchantId	Mandatory	Merchant ID of the child merchant for which the split is to be added.
value	Mandatory	Amount to be settled to that child merchant account
Commission	Mandatory	Aggregator's commission in this particular split.
Description	Optional	Summary of the split.

The format of the json encoding for productinfo is as follows:-

productinfo = {"paymentParts":[{

"name":"splitId1",

"merchantId ":"4510911",

"value":"10",

"commission" : "5",

"description":"splitId1 summary"

},

{

"name":"splitId2",

"merchantId ":"4510912",

"value":"10",

"commission" : "5",

"description":"splitId2 summary"

}]

}

There are certain checks on the parameters in json –

(1) The sum of value and commission of all the splits should be equal to the total transaction amount (parameter name - amount).

(2) The merchantId pass should be linked to the aggregator merchant.

Note – If any of the above checks fail, you will get this error – Sorry, some problem occurred.

The parameters to post are described below:

S.No	Variable	Importance	Description
1	key	Compulsory	Merchant Key provided by PayUMoney
2	txnid	Compulsory	
3	amount	Compulsory	Payment amount (Type cast the amount to float)
4	productinfo	Compulsory	Payment parts json as discussed in the point number 6.
5	firstname	Compulsory	(only alphabets a-z are allowed)
6	lastname		(only alphabets a-z are allowed)
7	address1		(Length of address1 and address2 must not more than 100 characters each and the allowed characters are only) A TO Z, a to z, 0 to 9, @, - (Minus), _ (Underscore), / (Backslash), (Space), (Dot)
8	address2		(allowed characters are same as for address1)
9	city		(allowed characters are same as for address1)
10	state		(allowed characters are same as for address1)
11	country		(allowed characters are same as for address1)
12	zipcode		Numeric value only
13	email	Compulsory	Customer's email Id
14	phone	Compulsory	mobile number or landline number (numeric value only)
15	shipping_firstname		Self-Explanatory (constraints same as firstname) Used in case of COD
16	shipping_lastname		Self-Explanatory
17	shipping_address1		Self-Explanatory
18	shipping_address2		Self-Explanatory
19	shipping_city		Self-Explanatory
20	shipping_state		Self-Explanatory
21	shipping_country		Self-Explanatory
22	shipping_zipcode		Self-Explanatory
23	shipping_phone		Self-Explanatory
24	shipping_phoneverified		Self-Explanatory (yes/no) Used in case of COD
25	udf1		user defined field 1
26	udf2		user defined field 2
27	udf3		user defined field 3
28	udf4		user defined field 4
29	udf5		user defined field 5
30	surl	Compulsory	Success URL where PayUMoney will redirect after successful payment.
31	furl	Compulsory	Failure URL where PayUMoney will redirect after failed payment.
32	curl		Cancel URL where PayUMoney will redirect when user cancel the transaction.

33	hash(Checksum)	Compulsory	Hash or Checksum =sha512(key|txnid|amount|productinfo|firstname|email|udf1|udf2|udf3|udf4|udf5||||||salt) (SALT will be provided by PayUMoney)
34	service_provider	Compulsory	payu_paisa

Important Things to remember:

Allowed characters for address1, address2, city, state, country, productinfo, email, and phone are:

1. Characters: A to Z, a to z, 0 to 9
2. - (Minus)
3. _ (Underscore)
4. @ (At the Rate)
5. / (Slash)
6.   (Space)
7. . (Dot)

If the merchant sends any other special characters then they will be automatically removed. The address will consider only first 100 characters.

Formula for checksum before transaction

sha512 (key|txnid|amount|productinfo|firstname|email|udf1|udf2|udf3|udf4|udf5||||||<SALT>)

SALT will be provided by PayUMoney. The algorithm used is SHA2 which is globally well known algorithm. To need help with implementation, feel free to call us, mail us or use Google to find the desired function library.

Formula for checksum after transaction

This time the variables are in reverse order and status variable added between salt and udf1

sha512(<SALT>|status||||||udf5|udf4|udf3|udf2|udf1|email|firstname|productinfo|amount|txnid|key)

It is strongly recommended that the hash (or checksum) is computed again after the transaction and is compared with what we post in the return parameters below.

Return Parameters

S. no.	Variable	Description
1	mihpayid:	Unique id from PayU.in
2	mode:	'CC' for credit-card / 'NB' for net-banking / 'CD' for cheque or DD / 'CO' for Cash Pickup
3	status:	success/pending/failure
4	key:	Merchant key provided by PayUMoney
5	txnid:	Merchant Transaction ID
6	amount:	Original amount send by merchant
7	discount:	This is discount given to user - based on promotion set by merchants.
8	productinfo:	<Self Explanatory>
9	firstname:	<Self Explanatory>
10	lastname:	<Self Explanatory>
11	address1:	<Self Explanatory>
12	address2:	<Self Explanatory>
13	city:	<Self Explanatory>
14	state:	<Self Explanatory>
15	country:	<Self Explanatory>
16	zipcode:	<Self Explanatory>
17	email:	<Self Explanatory>
18	phone:	<Self Explanatory>
19	udf1:	<Self Explanatory>
20	udf2:	<Self Explanatory>
21	udf3:	<Self Explanatory>
22	udf4:	<Self Explanatory>
23	udf5:	<Self Explanatory>
24	hash:	Hash must be verified before confirmation of transaction
25	Error:	If transaction failed, then reason of failure (Refer to APPENDIX at the end of the document)
26	PG_TYPE	Payment gateway type used in transaction
27	bank_ref_num	Reference number for the payment gateway (received in PG_TYPE)
28	shipping_firstname	<Self Explanatory>

29	shipping_lastname	\<Self Explanatory>
30	shipping_address1	\<Self Explanatory>
31	shipping_address2	\<Self Explanatory>
32	shipping_city	\<Self Explanatory>
33	shipping_state	\<Self Explanatory>
34	shipping_country	\<Self Explanatory>
35	shipping_zipcode	\<Self Explanatory>
36	shipping_phone	\<Self Explanatory>
37	shipping_phoneverified	\<Self Explanatory>
38	unmappedstatus	Status of transaction in PayU's system e.g. initiated/ in progress /dropped / bounced / captured / auth/ failed / user cancelled/ pending
39	payuMoneyId	Unique payment ID

Checksum Algorithm Example codes

The **Checksum algorithm** used is SHA512 which is globally well known algorithm. To need help with implementation, feel free to call us, mail us or use Google to find the desired function library for your implementation. Some example codes are also mentioned below:

For PHP
Example code:

$output = hash("sha512", $text);

For .NET
Link: http://msdn.microsoft.com/en- us/library/system.security.cryptography.sha512.aspx Example code:
byte[] data = new byte[DATA_SIZE];

byte[] result;

SHA512 shaM = new SHA512Managed();

result = shaM.ComputeHash(data);

For JSP

Example code:

import java.io.FileInputStream;

import java.security.MessageDigest;

```
public class SHACheckSumExample

{

public static void main(String[] args)throws Exception

{

MessageDigest md = MessageDigest.getInstance("SHA-512"); FileInputStream fis = new
FileInputStream("c:\\loging.log");

byte[] dataBytes = new byte[1024];

int nread = 0;

while ((nread = fis.read(dataBytes)) != -1)

{ md.update(dataBytes, 0, nread);

};

byte[] mdbytes = md.digest();

//convert the byte to hex format method

1 StringBuffer sb = new StringBuffer();

for (int i = 0; i < mdbytes.length; i++) {

sb.append(Integer.toString((mdbytes[i] & 0xff) + 0x100, 16).substring(1));

}

System.out.println("Hex format : " + sb.toString());

//convert the byte to hex format method 2

StringBuffer hexString = new StringBuffer();

for (int i=0;i<mdbytes.length;i++) {

hexString.append(Integer.toHexString(0xFF & mdbytes[i]));

}

System.out.println("Hex format : " + hexString.toString());

}

}
```
